

A UNIFIED MULTIPLIER TRIPLE-EXPANSION SCHEME AND EXTRA REGULAR COMPACT LOW-POWER IMPLEMENTATIONS WITH BORROW PARALLEL COUNTER CIRCUITS

GOVERNMENT RIGHTS

This invention was funded, at least in part, under grants from the National Science Foundation, Nos. MIP-9630870, CCR-0073469 and New York State Office of Advanced Science, Technology & Academic Research (NYSTAR, MDC) No. 1023263. The Government may therefore have certain rights in the invention.

BACKGROUND OF THE INVENTION

1. Field of the Invention

The present invention relates generally to very large-scale integrated (VLSI) circuits and more specifically to low-power, high-performance, self-testing VLSI multiplier circuits having a reduced number of transistors.

2. Description of Related Art

The $(n \times n-b)$ bit high-performance multiplier designs, where $n \geq 10$, often have the following major disadvantage. Both, Booth and non-Booth designs (see, A. D. Booth, A Signed Binary Multiplication Technique, *Quart. J. Mech. Appl. Math.*, vol. 4, 1951), are constructed based on the schemes of generation and reduction of a single large partial product bit matrix, usually with Wallace tree structure processing in parallel (see, C. S. Wallace, A Suggestion For A Fast Multiplier, *IEEE Trans. Electronic Computers*, Vol. Ec-13, 1964, pp. 14-17). The schemes are intrinsically irregular and not exhaustively self-testable, e.g., requiring built-in test circuits. This is due to the initial partial product bit matrix having a triangle or trapezoid shape, and the multiplier circuits having low controllability and observability for test, particularly for the most commonly used Booth multipliers. The area cost, power cost, layout cost, and the test cost in dealing with such irregularities are significant.

The functions of conventional multipliers are divided into three stages, the generation stage of the partial products, followed by the adding stage of the partial products, and the last stage of the final addition. Since the last stage usually employs a standard fast adder, it is often excluded from the discussion.

Two recently proposed designs, seen as the typical examples of the improved conventional architectures, are the rectangular-styled Wallace tree multiplier (RSWM) described in N. Itoh, Y. Naemura, H. Makino, Y. Nakase, T. Yushihara, Y. Horiba, "A 600MHz, 54 x 54-bit Multiplier With Rectangular-Styled Wallace Tree", *IEEE JSSCs*, Vol. 35, No2, February 2001, (Itoh) and the limited switch dynamic logic multiplier (LSDL) described in Robert Montoye, Wendy Belluomini, Hung Ngo, Chandler McDowell, Jun Sawada, Tuyet Nguyen, Brian Veraa, James Wagoner, Mike Lee, "A Double Precision Floating Point Multiplier" Proc. of 2003 *IEEE ISSCC*, February, 2003. (Montoye)

The RSWM design proposes a rectangular Wallace-tree construction method. In this method, the partial products are divided into two groups and added in the opposite directions. The partial products in the first group are added downward, and the partial products in the second group are added upward. This method eliminates the dead area that occurs in a general Wallace tree design. It also optimizes the carry propagation between the two groups to realize the high speed and a simple layout. Applying the method to a 54 x 54 bit multiplier, a 980 mm x 1000 mm (0.98 mm²) area size and a 600-MHz clock speed have been achieved using 0.18 mm Complementary Metal Oxide Semiconductor (CMOS) technology.

The LSDL multiplier design proposes a method of merging pre-charged dynamic logic into the input of every latch, which differs for circuits merging logic and latches described in Daniel W. Dobberpuhl, Richard T. Witek, Randy Allmon, Robert Anglin, David Bertucci, Sharon Britton, Linda Chao, Robert A. Conrad, Daniel E. Dever, Bruce Gieseke, Soha M. N. Hassoun, Gregory W. Hoepfner, Kathryn Kuchler, Maureen Ladd, Burton M. Leary, Liam Madden, Edward J. McLellan, Derrick R. Meyer, James Montanaro, Donald A. Priore, Vidya Rajagopalan, Sridhar Samudrala, and Sribalan Santhanam, "A 200-MHz 64-b Dual-Issue CMOS Microprocessor", *IEEE JSSCs*, Vol. 27, No11, November 1992 (Dobberpuhl). In Dobberpuhl, clocks are used to tri-state the output of a static logic gate, while in LSDL multipliers clocks are used to control pre-charge and evaluation phases of dynamic logic and latch the outputs. This allows most of the speed advantages of the dynamic logic to be preserved while eliminating most of the traditional dynamic logic power penalty. The LSDL design achieves a 2.2 GHz 53 x 54 pipelined multiplier, fabricated in 0.13 mm CMOS technology with an area of 315 mm x 495 mm (0.155 mm²) which reduces the area required by RSWM design by 50% (scaled for technology) and increases the operation frequency at the same time.

Both RSWM and LSDL multipliers are Booth encoded Wallace tree designs and have yielded multipliers with great performance and cost reduction in terms of an area or area-power. However, the design complexities in both RSWM and LSDL multiplier are increased accordingly. The RSWM design uses a high-speed redundant binary (RB) architecture (see Dobberpuhl), a complex optimization process, and an extra area for carry-signal propagation to add upward partial products in the lower-bit group. The LSDL design requires well-controlled dynamic circuit and clock design with proper pulses, long enough for evaluation of the dynamic logic and short enough to prevent a significant leakage on the dynamic node.

Furthermore, the RSWM and LSDL design requires relatively expensive custom processing in laying out of most of its circuits. Finally, building test circuitry is required in both of these designs.

SUMMARY OF THE INVENTION

A unified, extra regular, complexity-effective, high-performance multiplier construction method is discussed and is applicable to a whole spectrum of $n \times n$ -b pipelined or non-pipelined multipliers for $10 \leq n \leq 81$, with no more than two levels of tripling processing for each construction. The method includes a library containing 3-b to 9-b borrow parallel small multipliers, used for compact, low-power implementation.

The multipliers are based on the novel counter circuitry, called borrow parallel counter, which utilizes 4-b 1-hot encoded signals and borrow bits, i.e., bits weighted 2. The multiplier circuit comprises at least two input numbers, each trisected into three segments, a plurality of Carry Select Adders (CSAs), a plurality of 3-b to 9-b borrow parallel small multipliers interconnected to the CSAs. The small multipliers are arranged to minimize the interconnection to the CSAs, and a plurality of output bits.

The small borrow parallel multiplier process bit input, and comprise an array including a plurality of identical counters with a simple layout arranged in a plurality of columns, wherein the "borrow-effect" naturally re-arranges bits being processed so that an actual number of bits processed in each column are balanced; minimal line connections within each line, wherein a single counter is used in each column; and a plurality of output bits most having similar delay, wherein the multiplier requires little cost in transistor sizing and delay equalization.

Exemplified by a 54 x 54-b (bit) multiplier, the method allows large multipliers to be generated from smaller multipliers, tripling the size in each expansion (6 x 6-b to 18 x 18-b to 54 x 54-b). This significantly reduces the complexity of state of the art designs and achieves full self-testability without sacrificing high-performance.

The triple expansion method optimizes only one column of a plurality of CSA block columns in a multiplier processing a plurality of bit inputs. The method provides a first level of application of a triple expansion scheme $P \times P$, where P is $(3m+z1)$, m is an integer multiplier, and $z1$ is $\{0, 1, -1\}$; and when required expanding the first level of application according to a $E \times E$, where E is $(3P+z2)$ and $z2$ is $\{0, 1, -1\}$.

BRIEF DESCRIPTION OF THE DRAWINGS

The foregoing and other objects, aspects, and advantages of the present invention will be better understood from the following detailed description of preferred embodiments of the invention with reference to the accompanying drawings that include the following:

Figure 1 is a diagram of the trisect-decomposing 18 x 18 product partial matrix according to the present invention;

Figure 2 is a diagram of the triple-expanded 18 x 18-b multiplier of the present invention, including Carry Select Adders (CSAs) outputs;

Figure 3 is a diagram of the triple-expanded 54 x 54 Multiplier of the present invention;

Figures 11A-11D are diagrams of the decomposition of $(3m+1) \times (3m+1)-b$ ($m=5$) bit matrix, partial product matrix, implementation of the $16 \times 16-b$ multiplier and rectangular structure of the $(3m+1) \times (3m+1)-b$ multiplier, respectively, of the present invention;

Figures 12A-12D are diagrams of the decomposition of $(3m-1) \times (3m-1)-b$ ($m=4$) bit matrix, partial product matrix, implementation of $16 \times 16-b$ multiplier and rectangular structure of the $(3m+1) \times (3m+1)-b$ multiplier, respectively, of the present invention;

Figures 13A-13D are diagrams of the modified decomposition of $(3m+1) \times (3m+1)$ -b ($m=5$) bit matrix, partial product matrix, implementation of 16×16 -b multiplier and rectangular structure of the modified $(3m+1) \times (3m+1)$ -b multiplier of the present invention; and

Figures 14A-14D are a diagram of the modified decomposition of $(3m-1) \times (3m-1)$ -b ($m=4$) bit matrix, partial product matrix, and the implementation of 11×11 -b multiplier and rectangular structure of the modified $(3m-1) \times (3m-1)$ -b multiplier of the present invention.

DETAILED DESCRIPTION OF THE INVENTION

The present invention provides a new multiplier triple-expansion scheme. The scheme is developed based on the work described in R. Lin, "Reconfigurable Parallel Inner Product Processor Architectures", *IEEE T LSI*, Vol. 9, No. 2. April 2001, pp. 261-272 (hereinafter "RL1"); R. Lin. and R. B. Alonzo, "An Extra-Regular, Compact, Low-Power Multiplier Design Using Triple-Expansion Schemes and Borrow Parallel Counter Circuits," in Proc. of workshop on Complexity-Effective Design (WCED, ISCA), Held in conjunction with the 30th Intl. Symposium on Computer Architectures, San Diego, CA, June 2003; and R. Lin, "Borrow Parallel Counters And Borrow Parallel Small Multipliers" and "Triple-Expanded Multipliers". New Tech. Disclosures of SUNY, August 2002, also respectively described in U.S. Provisional Patent Applications Nos. 60/431,372 and 60/431,373, (hereinafter "RL2"), which are both incorporated herein by reference.

The present invention provides improved performance through use of a new partial product bit matrix decomposition method as well as a novel extra-compact, low-power large parallel counter circuitry. The present invention is an improvement over the conventional large Booth multipliers, and is highly regular and compact in layout. The inventive scheme can be exhaustively tested without extra built-in test circuits.

The decomposition and re-arrangement of the bit matrices provided by the scheme of the present invention significantly reduces the number of recursive levels required for the construction of large multipliers, in particular to no more than two. Furthermore, the present scheme handles decomposition of any type of partial product matrix, without being restricted to $2m \times 2m$ or $3m \times 3m$ only. More specifically, the inventive scheme handles decomposition of $n \times n$ matrices with $n=3m$, $3m+1$ and $3m-1$ in a similar manner. This allows for application of the scheme to the whole spectrum of multiplier designs with the same efficiency.

The building block of the inventive multiplier is a novel CMOS parallel counter circuitry, utilizing 4-b 1-hot encoded signals, and borrow bits, i.e., bits weighted two. The borrow parallel counter circuits greatly simplify the structures of small multipliers, as a single array of almost identical counters, and improve the compactness and effectiveness of the circuit layout. The circuit layout contributes significantly to the efficient implementation of the triple expanded multipliers. It should be noted that in addition to using the provided borrow parallel small multipliers for the implementation of the inventive scheme, those skilled in the art will readily recognize that other small multipliers may be used as well by the inventive scheme.

Based on the preliminary layouts and simulations, the proposed 54 x 54-b pipelined multiplier, as a typical example, is implemented in an area of $434.8 \times 769.5 = 334,578.6 \text{ m}^2$ with a 0.18 μm technology, achieving a 1GHz at 1.8V supply and a good low-power performance. The area is 37.9% of the area of RSWM design, or 75.8% of the LSDL area (scaled for technology).

18 x 18 Multipliers

Figures 1 and 2 illustrate an 18 x 18-b virtual multiplier 10, which produces two output numbers instead of one. The multiplier 10 is constructed using nine 6 x 6-b small multipliers 12 and five adders 20-28, using a trisect decomposition approach. Two 18-b input numbers 16 are first trisected into input group-bits or six bit segments a, b, c 40 and x, y, z 42, partitioned, and distributed to nine 6 x 6-b multipliers 12, where the 6 x 6 partial product matrices are generated and the nine 12-b products are produced. The adders 20-28 then add weighted bits of the nine products. The weight range 18 of each bit group, received by the adders, is indicated by a number, 1 to 5, at the top of each adder or receiver block 20-28.

In Figure 1, adder-3a (20) adds three 6-bit numbers to result in the final sum's bits 6 to 11 and carries to adder-5a (22). Adder-5a (22) then adds five 6-bit numbers (and the carry-ins) to result in the final sum's bits 12 to 17 and carries to adder-5b (24). Similarly, adder-5b (24) adds five 6-b numbers and adder-3b (26) adds three 6-b numbers to result in final sum's bits 18 to 23 and bits 24 to 29 respectively. The carry-out bits from adder-5b (24) will be added by the last adder, adder-c (28), to result in the six most significant bits (MSB). Usually no addition is required for the output bits 0 to 5. All 36 bits of the product have been correctly produced.

Figure 2 illustrates a triple-expanded 18×18 multiplier schematic re-positioned along its inputs distribution. Because small multipliers are independent of receiving inputs, (trisected segments of the input numbers) and carrying out multiplications, they can be re-arranged to minimize the interconnection between the small multipliers and the Carry Select Adders (CSAs) 14 with 2 levels of 3:2 (30) and 4:2 (32) counters plus a latch for each output bit. The two 18-b input numbers J and K 16 are trisected into segments: a, b, c 40 and x, y, z, 42 each of 6 bits. They are distributed to the 9 small multiplier blocks. Since the 18×18 multipliers are virtual multipliers, each providing two output numbers, no final addition is required.

54 x 54 Multiplier

When the inventive circuit scheme is applied recursively for one more level, it results in the 54×54 -b multiplier 100 illustrated in Figure 3. The inventive circuit 100 comprises nine 18×18 -b triple-expanded virtual multipliers 112 and a level of CSAs adders called level-2 CSAs 114, which is a row of 2 levels of binary (4, 2) and (6, 2) counters 132, 134 plus latches, residing at the bottom of the 54×54 -b multipliers 100. The outputs (two-number pairs) of the CSA adders 114 are sent to the fast final adder, which is not shown.

The process (excluding the final addition) requires three stages of pipelined operations:

- (1) base, i.e., 6×6 -b virtual multiplication,
- (2) level-1, i.e., 18×18 -b bit reduction, and
- (3) level-2 bit reduction.

Since these three operations require comparable delays, the scheme fits well for a 3-stage (or 3.5-stage) pipelining and multiply-accumulate implementations. Two output numbers, of 18×18 multiplier 112 each, are routed to the CSAs 114 in parallel, passing through zero or three or six rows of 6×6 multipliers. Since the height of each 6×6 multiplier 150, illustrated in Figure 4a is made as short as possible, the interconnection distance is minimized.

Efficient small multipliers of any magnitude may be considered as bases for the triple expansion to yield large multipliers. In an exemplary embodiment the present invention has adopted two types of 6×6 multipliers shown in Figures 4a and 4b respectively. The multiplier 150 of Figure 4a is a small (3,2)-(4,2) counter based Wallace-tree style multiplier, described in R. Lin, "Low-Power High-Performance Non-Binary CMOS Arithmetic Circuits," in *Proc. of 2000 IEEE Workshop on*

SIGNAL PROCESSING SYSTEMS (SiPS), Lafayette, Louisiana, October, 2000, pp. 477-486

(hereinafter "RL3"). The multiplier 152 of Figure 4b is a borrow parallel small multiplier which is a single array of a borrow parallel counter. The counter circuits will be described in detail below. Both multipliers receive two 6-bit input numbers, J and K, 16 (Figure 1), generate a small partial product bit matrix and then reduce it into two numbers P (p10-p0) and Q (q10-q5), so that $J \cdot K = P + Q \cdot 2^5$. The (4,2)-(3,2) based 6x6 multiplier 150 of Figure 4a uses slightly fewer transistors, while the borrow parallel 6 x 6 multiplier 152 of Figure 4b has a more compact layout and mainly performs logic with 4b-1-hot signals that feature lower switching activity and use fewer hot lines.

4-b 1-Hot Borrow Parallel Counters

Parallel counter circuits utilize 4-b (bit) 1-hot or non-binary signals. Each encoded signal has 4, instead of 2, signal lines with only one of these signals being logic level high at any time. Such signals, representing integers ranging from 0 to 3, are shown in Table 1.

These parallel counter circuits are superior in several aspects, including speed and power, when compared with traditional binary counters for multiplier designs described in RL1, RL2 and RL3, referenced above. However, to reduce 7 bits into 3 or 2 bits, the previously proposed circuits require 8 to 10 additional transistors for signal type conversion, from non-binary to binary.

The new family of circuits, called borrow parallel counters, including 5_1, 5_1_1, 6_1, and 6_0, does not require type conversion, and requires a minimum number of transistors with a large ratio of negative-channel Metal Oxide Semiconductor (nMOS)/ positive-channel Metal Oxide Semiconductor (pMOS), and yet shows superior layout and performance. As shown in Figures 5 and 6, the counter not only utilizes both 4-b 1-hot signal encoding and borrow bits, i.e., input bits weighted 2 instead of 1, but also provides an embedded full adder adding non-binary (4-b-1-hot) and binary signals without type conversion. For example, if the non-binary signal $R=0100=2$ is produced, additional circuits are usually required to convert it into two bits, i.e., $s_0=0$, $s_1=1$, before it can be used by a conventional circuit. This leads to a significant reduction in circuit complexity. The circuit is on its way to become a new type of a building block, replacing traditional (2, 2), (3, 2), i.e., half-adder, full-adder, and (4, 2) parallel counters for some arithmetic processor designs.

Figure 5 illustrates a parallel counter 154 designated 5_1 borrow parallel counter. The counter 154 includes five input bits A1-A5, and bit A5 weighted two. This parallel counter circuit and its variants possess the following three features:

- (1) Each counter, at high speed, reduces 5 or 6 input bits (one or two being borrowed bits) into 2 output bits, with a few in-stage carry in and out bits.
- (2) The majority of the transistors are gated by 4-b 1-hot signals, or used to pass 4-b 1-hot signals, as illustrated in Figure 6, which leads to the reduction of both switching activities and the flow of hot signals by about half of the normal (see RL1, RL2, RL3). The low-power features of the 5-1 borrow parallel counter are illustrated in Figure 5 by the bold lines 156 which show the 4-b 1-hot signal, and the double bold line 156 is for the 1-hot bit. The transistors in a dotted box 160 are gated by (used to pass) the 4-b 1-hot signal, which reduces switching activities and leakage.
- (3) The ratio of nMOS/pMOS is 2.4 (instead of 1 for traditional CMOS) and a compact layout can be achieved easily.

$R = \begin{matrix} r3 \\ r2 \\ r1 \\ r0 \end{matrix}$	$\begin{matrix} 0 \longrightarrow \\ 0 \longrightarrow \\ 0 \longrightarrow \\ 1 \longrightarrow \end{matrix}$	$\begin{matrix} 0 \longrightarrow \\ 0 \longrightarrow \\ 1 \longrightarrow \\ 0 \longrightarrow \end{matrix}$	$\begin{matrix} 0 \longrightarrow \\ 1 \longrightarrow \\ 0 \longrightarrow \\ 0 \longrightarrow \end{matrix}$	$\begin{matrix} 1 \longrightarrow \\ 0 \longrightarrow \\ 0 \longrightarrow \\ 0 \longrightarrow \end{matrix}$
decimal value of R	0	1	2	3
binary value of R = s1s0	00	01	10	11
binary value of s0 (encoded by R)	0	1	0	1
binary value of s1 (encoded by R)	0	0	1	1

Table 1

Table 1 shows the 4-b 1-hot encoding scheme. The unique bit positions determine the values of a 4-b 1-hot signal. The change of an R value from one signal to another causes the change of bit-values in no more than two lines, which reduces switching activity of the circuit. In addition at any logic stage there is only one hot bit on four signal lines, which reduces static leakage power.

Figure 6 shows a full adder circuit which adds three bits s0, s1 and Q, represented by two 4-b 1-hot signals and a binary signal without type conversion. The components and the typical application of the 5_1 borrow parallel counters are illustrated in Figures 8-10.

Referring to Figures 5 and 7, the 5₁ borrow parallel counter is shown to comprise seven components:

- (1) The 4-b 1-hot signal encoder, which encodes $(A1+A2+A3+A4) \bmod 4$ into $R=s0'+2s1'$, intermediate results $s0'$ and $s1'$ are not shown;
- (2) Adding-A5 that adds Xi , $s1'$ and $A5$. Note that $s0 + A5 \bmod 2 = s0$; no change for $s0$ is one of advantages of using borrow bits;
- (3) Q-generator that generates $q = (A1+A2+A3+A4 + 2A5)/4$;
- (4) R-restoration (R-res) that restores non-full swing 4-b 1-hot signal R into a full swing one;
- (5) , (6), and (7) Three stages (components) of the embedded full adder circuit as detailed in Figures 6 to 9. Each 5₁ borrow parallel counter co-works with its upper and lower neighbor 5₁ counters, as shown in Figure 9, to produce two output bits S and C . That is because $s0$, $s1$, and q within each counter are weighted 1, 2, and 4 respectively. The actual $s0$, $s1$, and q being added by the full adder are from three adjacent columns with $s0$ in the highest column, thus they have the same weight. There is no explicit data type conversion and the output is in binary form.

The inventive circuit simulations have shown the superiority of the new counters in comparison with the conventional ones in all aspects including delay, area, and power dissipation, which will be clearer when the circuits are applied in small multiplier designs. The 5₁ borrow parallel counter uses 78 transistors, about two thirds of which are nMOS cells, and 56 out of 78 (or 73%) of the transistors are either gated by or used to pass 4-b 1-hot signals, leading to a significant reduction in power-consuming activities. The inventive counter implements arithmetic Equation E1 and logic equations shown below.

$$A1 + A2 + A3 + A4 + 2A5 = s0 + 2s1 + 4Q \quad (E1)$$

$$Xo=s0; \quad Yo=Xi \text{ xor } s1; \quad Zo=Xi; \quad S=Yi \text{ xor } Q;$$

$$C= Zi \text{ and } Yi' \text{ or } Q \text{ and } Yi.$$

In these equations, s_0 , s_1 , Q are temporary parameters, and X_0 , Y_0 , Z_0 and X_i , Y_i , Z_i are in-stage carry (out/in) bits. The close variants of the 5_1 borrow parallel counter are denoted by 5_1_1, 6_1 and 6_0, which are similar to 5_1, except for the number of borrow bits, and the component for encoding those bits are slightly different. There is little change in complexity between 5_1 and 5_1_1 as well as between 6_1 and 6_0. The main application of the proposed borrow counters is, a novel technique to reduce in parallel the height of a weighted bit matrix with significant new features which is well suited to efficient Very Large-Scale Integration (VLSI) implementations of arithmetic circuit designs.

Borrow parallel counters may be used for efficient partial product bit reduction for large multiplier designs, e.g., 32b or larger. For example, a 96 transistor 6-1 borrow parallel counter (two output buffers may not be needed) can replace 4 full adders or two (4, 2) counters, possessing all advantages as described above without an increase in circuit transistor count. The simulation results for 5-1 and 5-1-1 borrow parallel counters are provided in Table 2 below.

6 x 6 Borrow Parallel Multipliers and the Base Multiplier Library

As a building block, the 6 x 6-b borrow parallel (virtual) multiplier shown in Figure 4b produces 17 output bits, or two numbers instead of one. Such an output form has two advantages:

1. It is fast. When the 7 least significant bits (LSBs) outputs are produced (through a ripple carry style process) the second 10 MSBs outputs are about ready (through carry save process).
2. It is useful for regular inter-connection and CSA bit reduction; as shown in Figures 2 and 3, the two output groups of each base 6 x 6 block are accurately separated with the lower weighted group as a 6-b number, while the higher weighted group as two 5-b numbers.

The multiplier is an array with five borrow parallel counters. When compared with conventional binary full-adder based counterparts, the small borrow parallel multiplier possesses the following features:

1. It is a single array of identical counters with a simple layout, since the “borrow-effect” naturally re-arranges the bits being processed so that the actual bits to each column are balanced.

2. It requires minimal line connections, since only a single counter is used in each column.

It gives the nearly same delay for almost all output bits, except a few faster outputs at two ends; therefore little cost is required in transistor sizing and delay equalization. The delay of the circuit of Figure 4b is about 0.6ns or 2 times a (4, 2) delay. Table 2 shows the summary of the parallel counters and small multiplier circuits.

circuit			area	$\frac{nMOS}{pMOS}$	0.18 μm 1.8V technology	
					delay (ns)	power ($\frac{\mu W}{MHz}$)

Table 2.

The library containing 3-b to 9-b small base multipliers is provided for compact, low-power implementation, illustrated in Figures 10a1-10a11.

Figure 10A1 shows the 3 x 3-b multiplier 200 constructed using a single 5_1 counter 202 plus a (2, 2) binary counter 204 and two restoration circuits with a carry bit plus two buffers 206 denoted by rt-c; the buffers may be unnecessary. Note that the inputs A6 to A8 do not need restoration and that A6 and A7 are weighted 2, while A8 is weighted 4.

Figure 10A2 shows the complete 3 x 3-b multiplier 210 with two bits as CSA outputs at position 4, i.e., p4 and q4.

Figure 10A3 is a 4 x 4 multiplier 212 consisting of similar components as the multiplier 200 (Figure 10A1) and with two bit outputs at positions 4 to 6. It should be noted at this time that all

virtual multipliers in this library (from 3 x 3-b to 9 x 9-b) have the same height, i.e., the height of a single 5_1, which provides the present invention with extra regularity and compact layout.

Figures 10A4 and 10A5 show two 5 x 5-bit multipliers 214, 216. The 5 x 5a multiplier 214 consists of special binary counters formed in a unit called 5_* 218. The multiplier 214 uses slightly larger area but is faster than the 5x5b multiplier 216 (Figure 10A5).

Figures 10A6 to 10A8 show three 6 x 6b multipliers 220-224. Multiplier 6 x 6a 220 is the best in speed but uses a larger area. Multiplier 6x6c 224 uses minimal area but produces one more bit in the outputs. Multiplier 6x6b 222 is slightly slower.

Figures 10A9 to 10A11 show virtual multipliers 7 x 7-b 226, 8 x 8-b 228, and 9 x 9-b 230 respectively. The 7 x 7-b multiplier 226 has a speed similar to 6 x 6-b ones, however, the 8 x 8-b multiplier 228 and the 9 x 9-b multiplier 230 are about one full-adder delay slower than 6x6-b multipliers. All these multiplier circuits 226, 228, 230 are faster than existing designs.

The Organization

The layouts of the 5-1 and 5-1-1 counters and the 6 x 6 multiplier in 180 μm CMOS technology (3 metal layers) are implemented to have areas of $12.87 \times 16.0 \mu\text{m}^2$ and $26.5 \times 85.5 \mu\text{m}^2$ respectively.

The design of two CSA blocks, i.e., level-1 and level-2 (14 and 114) shown in Figures 2 and 3, are regular structured and may have a layout with straightforward simplicity. The size of level-1 block 14 (Figure 2), including output latches, is estimated as $34.2 \times 85.5 \times 3 \mu\text{m}^2$. The size of level-2 block 114 (Figure 3) is about $48.7 \times 85.5 \times 9 \mu\text{m}^2$. The overall pipelined 54 x 54 multiplier may have a layout (4-metal-layer) in a rectangular area with a height of $((26.5 + 5) \times 3 + 34.2) \times 3 + 48.7 = 434.8 \mu\text{m}$ and a width of $85.5 \times 9 = 769.5 \mu\text{m}$, or the area of $434.8 \times 769.5 = 334,578.6 \mu\text{m}^2$. The area is about 37.9% of the area $882,000 \mu\text{m}^2$ of RSWM multiplier (see Itoh), excluding the final adder about 10% of the total area of $980,000 \mu\text{m}^2$, or 75.8% of the area of LSDL multiplier (see Montoye), scaled for technology.

The complexity reduction of the design can be seen from the high regularity of the multiplier logic scheme. Eighty-one identical 6 x 6 small multipliers, serving as building blocks, are organized in a 9 x 9 matrix form. The nine identical level-1 CSA adder blocks plus a single level-2 CSA block

require minimal custom design workload for optimal layouts. The inputs are organized in a routine network and a three level pipeline interconnection nets in highly regular structure.

The advantages of the design in terms of complexity-effectiveness, compared with the designs of RSWM (see Itoh) and LSDL (see Montoye) may include

- (1) simpler CMOS technology and layout;
- (2) significantly less amount of custom design work load;
- (3) significant area reduction without sacrificing high-performance: an expected pipeline frequency of 1GHz can be achieved;
- (4) low-power achieved through using the compact 4-b 1-hot counter circuitry;
- (5) modular and repeated components;
- (6) self-testable: It is directly provided by the triple expansion logic scheme.

The regular decomposition of partial product bit matrix enables the circuit possessing high controllability and observability for test, without using a built-in circuit. Exhaustive tests can be performed by testing 81 6 x 6 small multipliers separately, along with 9 level-1 CSA adder blocks and the level-2 adder block. The test vector length is practically feasible and is easily achieved through the use of an algorithm described in R. Lin and M. Margala, "Novel Design And Verification Of A 16 X 16-B Self-Repairable Reconfigurable Inner Product Processor", in *Proc. of 12th Great Lakes Symposium on VLSI*, NYC, April, 2002, (hereinafter "RL4"). The brief summary and comparison of the three large or floating-point multipliers are provided in Table 3.

multiplier	area mm ²	technology	area relative value (scaled for technology)	operation frequency GHz	power	self- testable
triple expanded	0.33	0.18 μ m 1.8 V	0.75	1	NA*	no
rectangular-styled Wallace tree (RSWM)	0.98	0.18 μ m 1.8 V	2	0.6	NA	no
limited switch dynamic logic (LSDL) 53x54	0.15	0.13 μ m 1.2 V	1	2	522 mW	yes

Table 3.

As described above, the multiplier has many low-power features, some of which are unique to the present invention; a low-power consumption of the processor can be reasonably predicted. The layout drafts for level-1 and level-2 CSA blocks are shown in Figures 10B1-10B7.

Figure 10B1 shows the general organization of a 54 x 54 triple-expanded multiplier 240 with 2-levels of CSAs with each 18 x 18 multiplier within a dotted box 242 and each 6 x 6 multiplier in a rectangle 244.

Figure 10B2 shows the internal connection of the 54 x 54-b triple-expanded multiplier 246. All 18x18-b multipliers 248, as well as 6 x 6-b multipliers 250, are identical except for receiving different input/output and connection lines. Input lines 252 and lines from each multiplier to level-1 CSA 254 are all 6-b each. Lines 256 from level-1 CSAs to level-2 CSAs are all 6-b each for single lines, 24-b each for bold lines.

Figures 10B3 to 10B5 show the line connections of an 18 x 18-b multiplier 260. The multiplier consists of three 6 x 6-b multipliers 262 plus a level-1 CSA block 264, each 6 x 6 multiplier 262 has a height of one (4, 2) or two (3, 2) counters and a width of 16.6 times the width of a (4, 2) or a (3, 2) counter (note that the (4, 2) and (3, 2) counters have the same width (see RL4). The experimental layout has shown the area is large enough for all lines to be efficiently connected with minimal or near minimal distance. All connections from the three 6 x 6 multipliers and mid-side (level-1 CSA 264) counters to the right side of the level-1 CSA 264, and the corresponding outputs of the CSA are shown in the Figures.

Figure 10B6 shows level-2 CSA block structure 270. All connections from 9 of the 18 x 18 multipliers to the 11 areas of level-2 CSA, i.e. A, B, C, E, F, G, I, J, K, L, M, with area D and H representing additional areas for outputs from F-E, C, and from G, I-J respectively. Notations in each of the areas of level 2 CSA 272, indicate as follows:

- 1:5-0 imply receiving one 6-bit number, as bit 0 to bit 5 of the output of an 18x18 multiplier;
- 2: 23-18 imply receiving two 6-bit numbers, each as bit 18 to bit 23 of the output of an 18x18 multiplier;
- (4, 2) x 6 implies adding the above numbers by 6 of (4, 2) counters;

$(6, 2) \times 12 + (4, 2) \times 6 = (3, 2) \times 60$ implies adding the above numbers by 12 of $(6, 2)$ binary counters plus 6 of $(4, 2)$ counters is equivalent to using 60 of $(3, 2)$ counters and layout draft for all areas and their boundaries shown in Figures 10B8 to 10B15.

Figure 10B7 illustrates symbolic and schematic definitions of the binary counter blocks $(6, 2) \times 3$ block 280, $(5, 2) \times 3$ block 282 and $(4, 2) \times 3$ block 284. For each schematic, three areas separated by bold lines represent three $(6, 2)$ s, or $(5, 2)$ s, or $(4, 2)$ s. Similar to the level-1 CSA block the level-2 CSA block has a fixed height of three $(3, 2)$ counters, instead of two $(3, 2)$ counters, and a width that matches the total width of remainder of the processor.

Figures 10B8 to 10B15 illustrate the calculation and experimental layout that have verified that the area used for the level-2 CSA block may be a perfect rectangle consistent with the regular and extra compact design of the whole 54×54 multiplier.

The total area of level-2 CSA block is as follows: Assuming the width and height of a $(3, 2)$ are $W (=5.2\text{mm, with the sharing of a ground or VDD})$ and $H (=14.1 \text{ mm})$ respectively, the total width is $\text{SUM}(\text{width}(A), \text{width}(B) \dots \text{width}(M)) = (4 + 16 + 16 + 12 + 4 + 16 + 16 + 12 + 5 + 16 + 16 + 8 + 4) (W) = 145 (W) = (752 \text{ mm})$, which closely matches the total width of remainder of the processor that is $(16.5 + 16 + 16.5)(W) \times 3 = 147(W \text{ or } 769.5 \text{ mm})$.

Unified Scheme: Design of a General $n \times n$ Multiplier

The method described so far is applicable to any $n \times n$ -b multiplier with $n = 3m$, where m is an integer. Below, this method is extended for $n=3m+1$ and $n=3m-1$, thus making the triple expansion method applicable to any $n \times n$ -b multiplier for all $n \leq 81$.

As shown in Figures 11 to 14 the decomposition of $(3m+1) \times (3m+1)$ -b and $(3m-1) \times (3m-1)$ -b partial product matrices are the same as that of a $3m \times 3m$ one, except that a few overlapped bits (two in each case) should be used in distribution of inputs, and a few (two in each case) special partial product bits should not be generated or should be set to zero. Two sub partial product matrix sizes are used in each case instead of one, however, the same sizes are in the same column, which makes each multiplier still in a perfect rectangular shape.

To see how this works, Figure 11A shows the decomposition of a $(3m+1) \times (3m+1)$ -b matrix 300, where a_0, c_0, x_0, z_0 are all 1-bit width, b_0 and y_0 are $(m-1)$ -b width, $a_1, b_1, b_2, c_1, x_1, y_1, y_2, z_1$

are $m-b$ width. The input of the two $(3m+1)$ -b numbers J and K is partitioned into a, b, c and x, y , and z respectively. They are all $(m+1)$ -b width, and there is one bit overlap between any of two contiguous columns among them. Such decomposition will make it easier to represent the partial product sub-matrices for a unified scheme.

Figure 11B illustrates the partial product matrix decomposition 302, which is similar to Figure 1 except that two types of sub-matrices are resulted. Three 1-b larger sub-matrices 304, i.e., $(m+1) \times (m+1)$ sub-matrices of m_2, m_6 , and m_7 are overlapped by a total of two bits. 0 bits in m_6 and m_7 imply that those bits are either set to 0 or not generated. To make the triple expansion scheme consistent with Figure 2, m_2 and m_7 are each defined to have one partial product bit (as shown) not being generated in multiplier 306 of Figure 11C, which makes the scheme correct. The multiplier 306 is a 16×16 multiplier implementing $(3m+1) \times (3m+1)$ for $m=5$, with input group-bits a, b, c overlapped and group-bits x, y, z overlapped, and where m_2, m_7, m_6 are 6×6 -b, others are 5×5 -b base multipliers. Since the height of sub-matrices are actually the same (no more than two input lines of differences between sub-matrices $(m+1) \times (m+1)$ and $m \times m$), the triple expansion scheme shown in Figure 11D will have the same perfect rectangular shape as shown in Figure 11D.

Figures 12A to 12D show the decomposition of partial product matrices of size $(3m-1) \times (3m-1)$, which is similar to that of $(3m+1) \times (3m+1)$ of Figures 11A to 11D. In Figure 12C 0 bits in m_4 and m_5 mean those bits are either set to 0 or not generated. The overlaps between m_4 and m_8 as well as m_5 and m_9 result in two partial product bits not being generated by m_4 and m_5 . In Figure 12C, the multiplier 318 with input group-bits a, b, c overlapped and group-bits x, y, z overlapped, and where m_2, m_7, m_6 are 3×3 -b, others are 4×4 -b base multipliers. In Figure 12D, for the $m \times m$ -b and $(m-1) \times (m-1)$ -b base multipliers, the heights are about the same.

The Optimized Scheme

Design of $(3m+1) \times (3m+1)$ and $(3m-1) \times (3m-1)$ Multipliers Based on a $3m \times 3m$ Multiplier

The unified scheme described in the last section can be optimized to design $(3m+1) \times (3m+1)$ and $(3m-1) \times (3m-1)$ multipliers with an existing $3m \times 3m$ multiplier. It is easy to see that using the scheme described in the last section, either of the designs requires the modification of both CSA blocks associated with columns 2 and 3. The optimized scheme will simplify the process so that the only CSA block needed to be modified is the one associated with the third column of the $(3m+1) \times (3m+1)$ or $(3m-1) \times (3m-1)$ multiplier.

To illustrate how this works, Figure 13A shows the decomposition of a $(3m+1) \times (3m+1)$ -b matrix 320, where each of a, b, x, y represents m -bit, b_1, c_1 and y_1, z_1 represents $(m+1)$ -bit, and a_1, x_1 represents $(m-1)$ -bit. Matrix 320 is the same as matrix 300 (Figure 11A), except that the values of a, a_1, b, b_1, c_1 and x, x_1, y, y_1, z_1 are defined differently. The input of two $(3m+1)$ -b numbers J and K is partitioned into a, b, c_1 and x, y, z_1 respectively, so that a, b, x, y are 5 -b numbers, c_1 and z_1 are 6 -b numbers. Also $b_1 = b$ plus the MSB of a , $a_1 = a$ minus the MSB of a , and $y_1 = y$ plus the MSB of x , $x_1 = x$ minus the MSB of x . Such decomposition will make it easier to represent the partial product sub-matrices for our unified scheme. Figure 13B illustrates the partial product matrix decomposition, which is similar to Figure 11B except that 0 bits in m_2 and m_7 mean those bits are either set to 0 or not generated (refer to Figure 13A for size measurements). Both m_2 and m_7 are $(m+1) \times (m-1)$ matrices, each with 4 generated bits (centered circles) moved to new positions (starts), indicated by arrows, plus the 0 bit forming an $m \times m$ matrix.

Three 1-b larger ones, i.e., $(m+1) \times (m+1)$ sub-matrices, now are m_3, m_9 and m_8 , instead of m_2, m_7 and m_6 as shown in Figure 13C, which makes the scheme correct, and can be obtained from only the modification of the CSA block associated with the third column of small multipliers. Since the height of the sub-matrices are actually the same (no more than two input lines of differences between sub-matrices $(m+1) \times (m+1)$ and $m \times m$), the triple expansion scheme shown in Figure 13C will have the same perfect rectangular shape as shown in Figure 13D. As shown in Figure 13C, the third column multipliers m_3, m_9, m_8 are 6×6 -b, and the others are 5×5 -b base multipliers. Inputs b_1, c_1, y_1 , and z_1 need to get an extra bit from their neighbor inputs (see Figures 13A and 13B). For the $m \times m$ -b and $(m+1) \times (m+1)$ -b base multipliers, the heights are about the same.

Figures 14A to 14D show decomposition for partial product matrices of size $(3m-1) \times (3m-1)$, which is a similar process as described above, except that the partition of the initial matrix and the size of the third column small multipliers are defined differently. The matrix 340 (Figure 14A) is the same as the matrix 300 (Figure 11A), except that the definitions of a, b, c and a_1, b_0, c_0 as well as x, y, z , and x_1, y_0, z_0 are defined differently. In Figure 14B 0 bits in m_2 and m_7 imply that those bits are either set to 0 or not generated. Both m_2 and m_7 are $(m+1) \times (m-1)$ matrices, each with 3 generated bits (centered circles) moved to new positions (starts), indicated by arrows, plus the 0 bit forming an $m \times m$ matrix. In the third column of multiplier 348 (Figure 14C), sub multipliers m_3, m_9, m_8 are 3×3 -b, and the others are 4×4 -b base multipliers. Also inputs b_1, c_1, y_1 and z_1 need to get an

extra bit removed and m_2, m_7 need to get an extra bit from neighbor inputs. As seen in Figure 14C, for the $m \times m-b$ and $(m-1) \times (m-1)-b$ base multipliers, the heights are about the same.

Rules for the number of base multipliers needed in a triple expansion are easy to verify and prove. These rules for multiplier triple expansion are as follows:

One-Level construction of $M \times M$ multiplier (for $10 \leq M=N \leq 27$ and $3 \leq m \leq 9$)

Case group A:

- (1) if $M = 3m-1$ requires two types of base multipliers: $m \times m-b$ and $(m-1) \times (m-1)-b$
- (2) if $M = 3m$ requires one type of base multipliers: $m \times m-b$
- (3) if $M = 3m+1$ requires two types of base multipliers : $m \times m-b$ and $(m+1) \times (m+1)-b$

Two-Level construction of $N \times N$ multiplier (for $28 \leq N \leq 81$, and $10 \leq M \leq 27$ and $3 \leq m \leq 9$)

Case group B: if $N = 3M-1$

- (4) if $M = 3m-1$ requires two types of base multipliers : $m \times m-b$ and $(m-1) \times (m-1)-b$
- (5) if $M = 3m$ requires two types of base multipliers : $m \times m-b$ and $(m-1) \times (m-1)-b$
- (6) if $M = 3m+1$ requires two types of base multipliers : $m \times m-b$ and $(m+1) \times (m+1)-b$

Case group C: if $N = 3M+1$

- (7) if $M = 3m-1$ requires two types of base multipliers : $m \times m-b$ and $(m-1) \times (m-1)-b$
- (8) if $M = 3m$ requires two types of base multipliers : $m \times m-b$ and $(m+1) \times (m+1)-b$
- (9) if $M = 3m+1$ requires two types of base multipliers : $m \times m-b$ and $(m+1) \times (m+1)-b$

Case group D: if $N = 3M$

- (10) if $M = 3m-1$ requires two types of base multipliers : $m \times m-b$ and $(m-1) \times (m-1)-b$
- (11) if $M = 3m$ requires one type of base multipliers : $m \times m-b$
- (12) if $M = 3m+1$ requires two types of base multipliers : $m \times m-b$ and $(m+1) \times (m+1)-b$

It should be noted that no more than two types of base multipliers are required to construct any $N \times N$ ($10 \leq N \leq 85$) multiplier.

Based on the unified triple expansion scheme, some examples of the multiplier constructions are presented as follows:

For 16×16 , 32×32 , 54×54 and 64×64 multipliers

16x16: One level of application of the Triple expansion scheme as follows:

One level: $M \times M = 16 \times 16 = (3m+1) \times (3m+1)$ for $m = 5$

Case 3, $M=16$, $m=5$, need two types of base multipliers: 5×5 -b and 6×6 -b

32x32: Two levels of application of the Triple expansion scheme as follows:

First level: $M \times M = 11 \times 11 = (3m-1) \times (3m-1)$ for $m = 4$

Second level: $N \times N = (3M-1) \times (3M-1)$ for $M = 11$

Case 4, $M=11$, $m=4$, need two types of base multipliers: 4×4 -b and 3×3 -b

54x54: Two levels of application of the Triple expansion scheme as follows:

First level: $M \times M = 18 \times 18 = 3m \times 3m$ for $m = 6$

Second level: $N \times N = 54 \times 54 = 3M \times 3M$ for $M = 18$

Case 11, $M=18$, $m=6$, need one type of base multipliers: 6×6 -b

64x64: Two levels of application of the Triple expansion scheme as follows:

First level: $M \times M = 21 \times 21 = 3m \times 3m$ for $m = 7$

Second level: $N \times N = 64 \times 64 = (3M+1) \times (3M+1)$ for $M = 21$

Case 8, $M=21$, $m=7$, need two types of base multipliers: 7×7 -b and 8×8 -b

For 23 x 23, 44 x 44, 72 x 72 and 81 x 81 multipliers

23x23: One level: $M \times M = 23 \times 23 = (3 \times 8-1) \times (3 \times 8-1)$ for $m = 8$

Case 1, $M=23$, $m=8$, need two types of base multipliers: 8×8 -b and 7×7 -b

44x44: First level: $M \times M = 15 \times 15 = 3m \times 3m$ for $m = 5$

Second level: $N \times N = 44 \times 44 = (3M-1) \times (3M-1)$ for $M = 15$

Case 5, $M=15$, $m=5$, need two types of base multipliers: 5×5 -b and 4×4 -b

72x72: First level: $M \times M = 24 \times 24 = 3m \times 3m$ for $m = 8$

Second level: $N \times N = 72 \times 72 = 3M \times 3M$ for $M = 24$

Case 11, $M=24$, $m=8$, need one type of base multipliers: 8×8 -b

81x81: First level: $M \times M = 27 \times 27 = 3m \times 3m$ for $m = 9$

Second level: $N \times N = 81 \times 81 = 3M \times 3M$ for $M = 27$

Case 11, $M=27$, $m=9$, need one type of base multipliers: 9×9 -b

While the invention has been shown and described with reference to certain preferred embodiments thereof, it will be understood by those skilled in the art that various changes in form and details may be made therein without departing from the spirit and scope of the invention as defined by the appended claims.
